'Airpocalypse' Hits Harbin, Closing Schools

The New York Times

October 21, 2013

School was canceled, traffic was nearly paralyzed and the airport was shut down in the northeast Chinese city of Harbin on Monday as off-the-charts pollution dropped visibility to less than 10 meters in parts of the provincial capital.

A dark, gray cloud that the local weather bureau described as “heavy fog” has shrouded the city of 10 million since Thursday, but the smoke thickened significantly on Sunday, soon after the government turned on the coal-powered municipal heating system for the winter.

“You can’t see your own fingers in front of you,” the city’s official news site explained helpfully. In the same vein, a resident of Harbin commented on Sina Weibo, the popular microblog platform, “You can hear the person you are talking to, but not see him.” Another resident added that he couldn’t see the person he was holding hands with.

The Harbin government reported an air quality index (AQI) score of 500, the highest possible reading, with some neighborhoods posting concentrations of PM2.5 — fine particulate matter that are 2.5 microns in diameter or smaller and especially harmful to health — as high as 1,000 micrograms per cubic meter, according to the China News Service.

Hazardous smog returns to Beijing and surrounding region amid holiday

Sunday, 06 October, 2013, 12:00am

Choking smog returned to blanket Beijing and surrounding areas yesterday, four days after a dangerous smog alert was lifted.

Meteorologists said pollution levels were likely to remain high until after the National Day "golden week" ends tomorrow - and the traffic crush as people returned from holiday would not help the problem.

The capital's air quality index registered above 300 for most of the day, according to the Beijing Municipal Environmental Monitoring Centre. That means the air was "severely polluted", the highest on the six-level scale. The National Meteorological Centre issued a yellow alert for haze for Beijing, Tianjin and parts of Shanxi and Hebei yesterday evening.

The US embassy's air-quality monitoring station showed that Beijing's air had been "very unhealthy" or "hazardous" since Friday night, with the level of PM2.5 - tiny particles that pose the highest health risks - reaching **372 per cubic metre** at 9am yesterday. The World Health Organisation recommends a daily limit of 20.

Public health, environmental and social determinants of health (PHE)

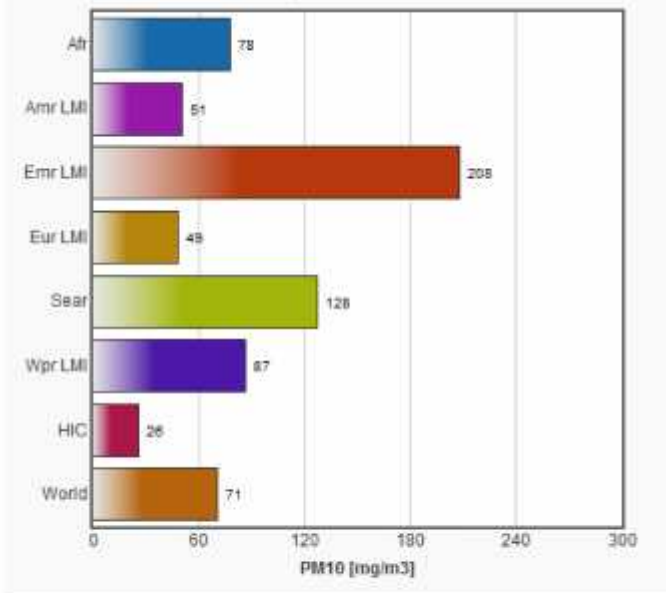

Ambient (outdoor) air pollution in cities database 2014

The database contains results of ambient (outdoor) air pollution monitoring from almost 1600 cities in 91 countries. Air quality is represented by annual mean concentration of fine particulate matter (PM10 and PM2.5, i.e. particles smaller than 10 or 2.5 microns).

The database covers the period from 2008 to 2013, with the majority of values for the years 2011 and 2012. The primary sources of data include publicly available national/subnational reports and web sites, regional networks such as the Asian Clean Air Initiative and the European Airbase, and selected publications. The database aims to be representative for human exposure, and therefore primarily captures measurements from monitoring stations located in urban background, residential, commercial and mixed areas.

The world's average PM10 levels by region range from 26 to 208 ug/m3, with a world's average of 71 ug/m3.

PM10 levels by region, for the last available year in the period 2008-2012

PM10: Fine particulate matter of 10 microns or less; Amr: America, Afr: Africa; Emr: Eastern Mediterranean, Sear: South-East Asia, Wpr: Western Pacific; LMI: Low- and middle-income; HI: high-income. PM10 values are regional urban population-weighted.

India admits Delhi matches Beijing for air pollution threatening public health

World Health Organisation study finds Indian capital had dirtiest atmosphere of 1,600 cities around the world for PM2.5 particles

Children protect their faces from Delhi's smog. The WHO said Delhi had a yearly average PM2.5 level of 153 – London's is a tenth of that. Photograph: Hindustan Times/Getty Hindustan Times/Getty

India's state air monitoring centre has admitted that pollution in Delhi is comparable to that of Beijing, but disputed a World Health Organisation (WHO) finding that the Indian capital had the dirtiest atmosphere in the world.

A study of 1,600 cities across 91 countries released on Wednesday by the WHO showed Delhi had the world's highest annual average concentration of small airborne particles (known as PM2.5) of 153.

What is Fine Particulate Air Pollution (PM_{2.5})?

- Anything collected on a filter
 - Solid particles or liquid droplets
 - Not gases

Deposition potential for particles of varying sizes

7 - 11 Microns

4.47 - 7 Microns

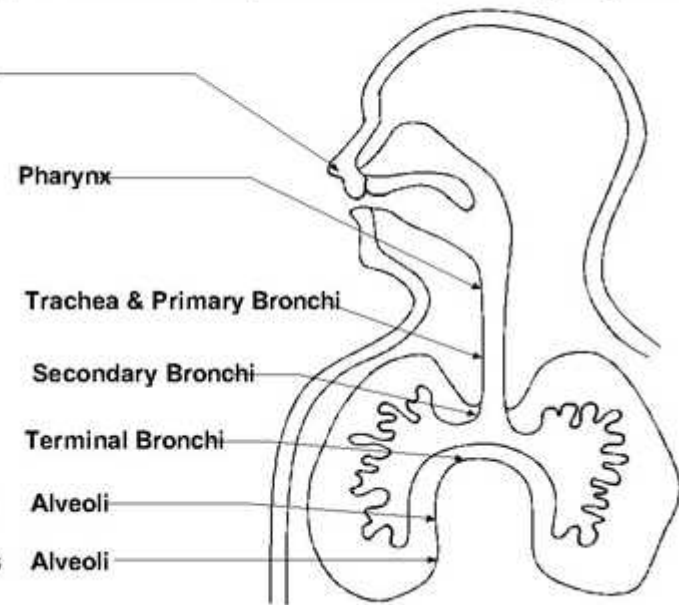

3.5 - 4.7 Microns

2.1 - 3.3 Microns

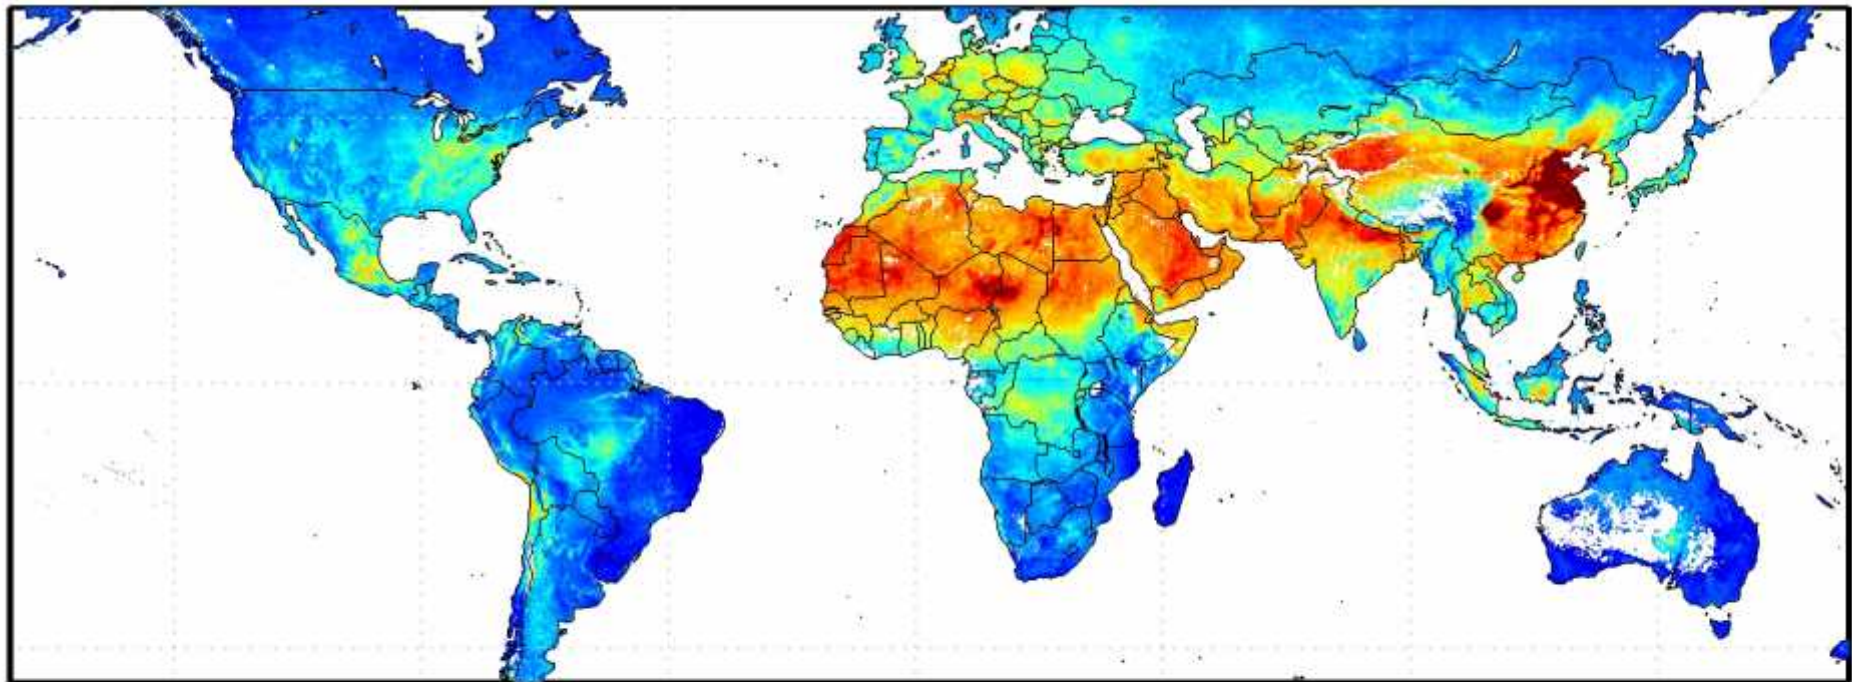

1.1 - 2.3 Microns

0.65 - 1.1 Microns

0.43 - 0.65 Microns

Comprehensive Dose-Response

What does this mean for the individual?

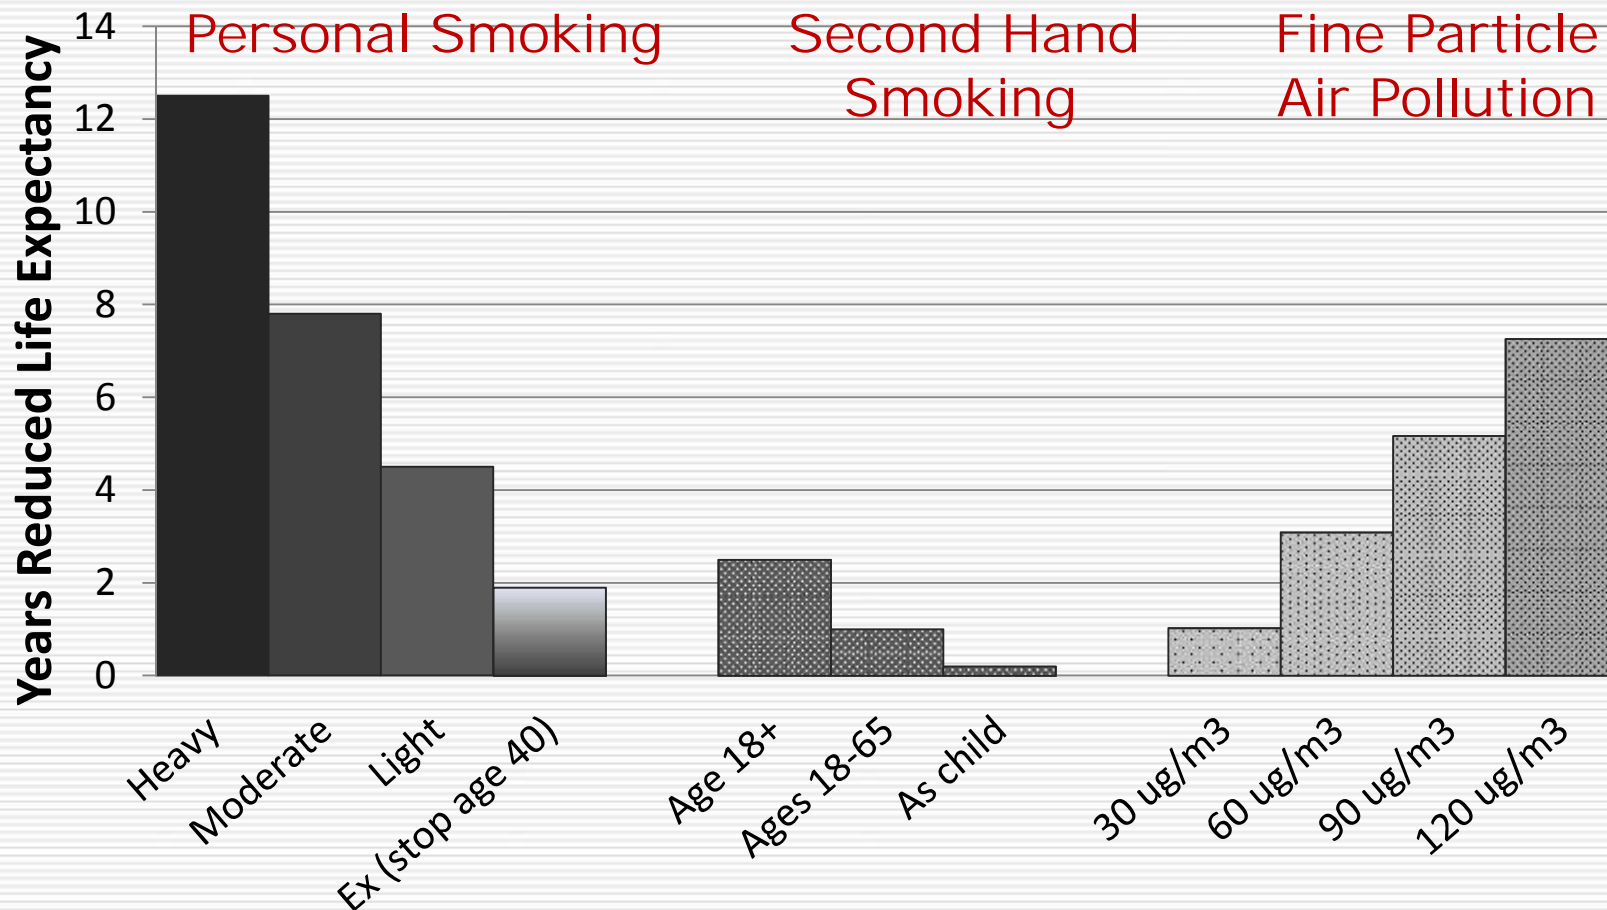

What is effect of life expectancy?

Survival curves 18-100 years and estimated life expectancy (LE) for alternative excess risk assumptions

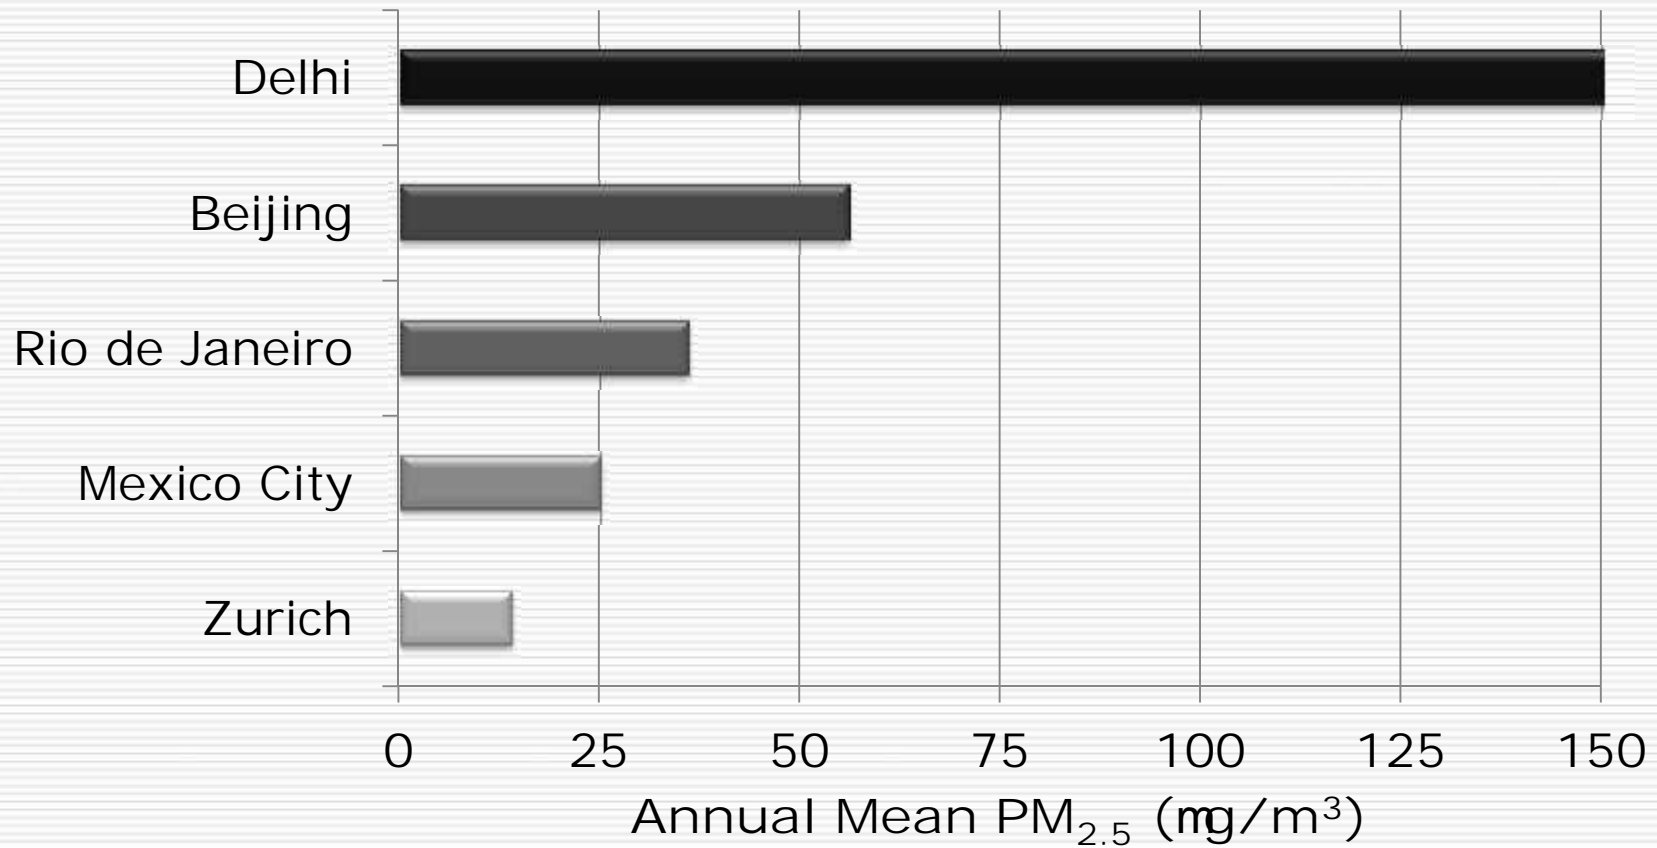

Estimated Years reduced life expectancy

- exposures to cigarette smoke and fine particle air pollution

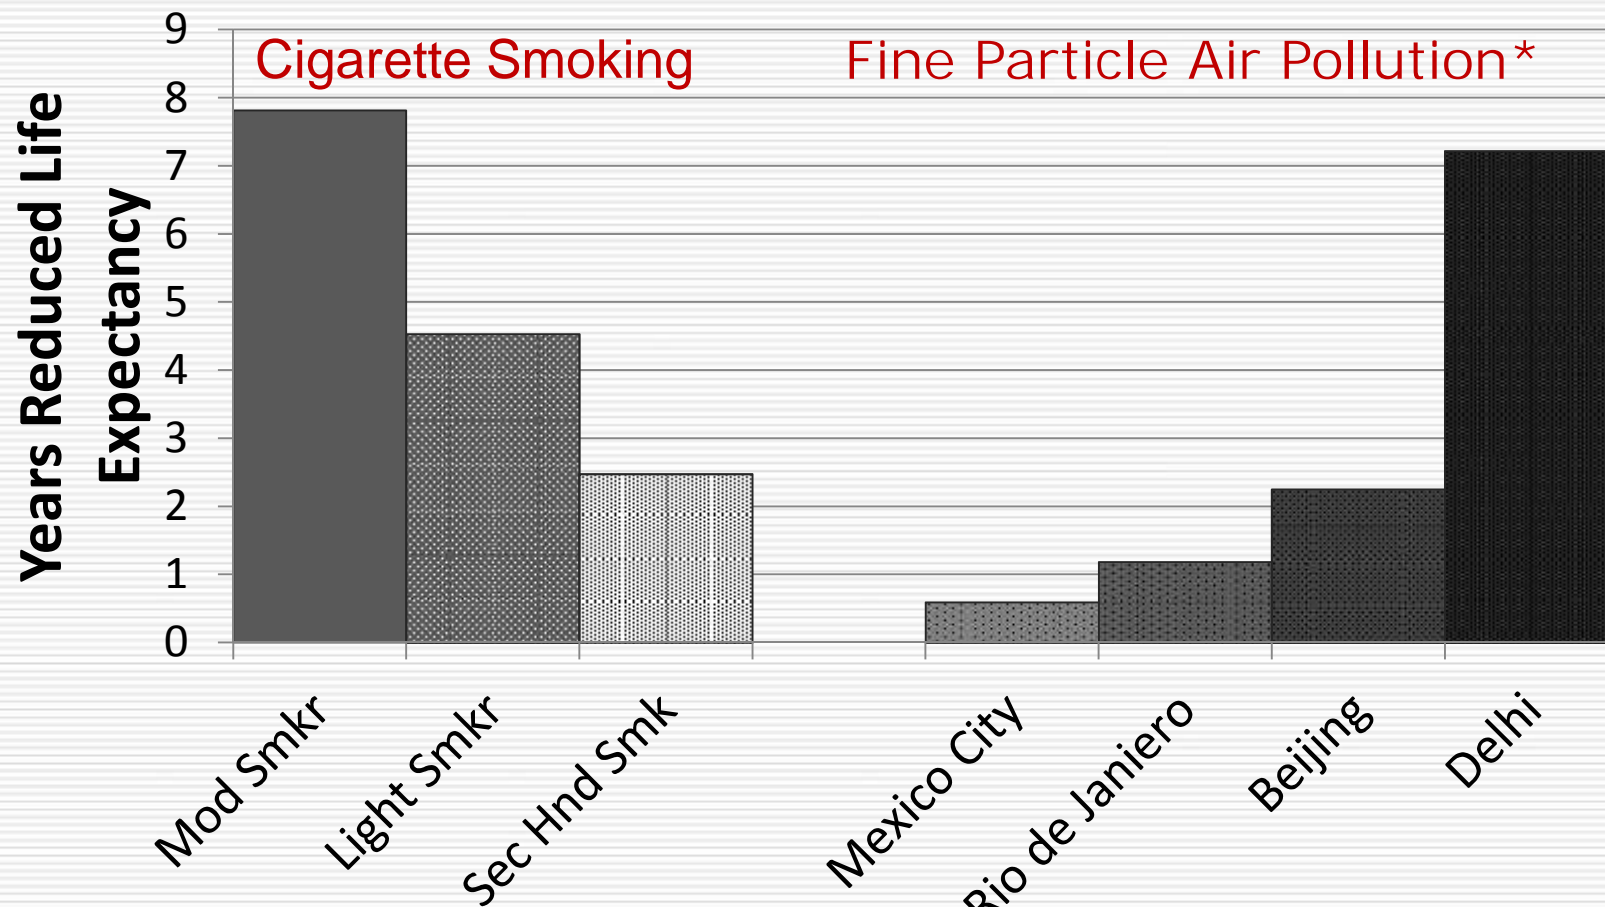

WHO Tabulation of PM_{2.5}

2012 Means – Cities

Years Reduced Life Expectancy - Lifetime Exposure

* Compared to Zurich

Incremental Risk

- Estimate of effect of each year of exposure
- Effect of potential changes in exposures or behaviors.
- Comparative risk for a worker or student who temporarily moves to such an environment.
- Consider 50-year old non-smoker who spends one year in mild, moderate, and high PM_{2.5} air pollution.

Estimated days of reduced life expectancy

1 year exposures to cigarette smoke and fine particle air pollution
50 years of age

* Compared to 15 ug/m3

Estimated days of reduced life expectancy

1 year exposures to cigarette smoke and fine particle air pollution
50 years of age

* Compared to Zurich

Effect of Age of living in Delhi?

- Baseline risk goes up with age
- Impact of each year of exposure to high pollution increases with age
 - 35 yrs – 29 days reduced LE
 - 50 yrs – 67 days reduced LE
 - 65 yrs – 116 days reduced LE

What does this mean for the individual?

- Not suggesting that their life is measurably shortened.
 - Rather these estimates reflect the increase probability of death in each year.
- How would they die?
 - Acute events such as myocardial infarction, stroke, asthma attack, or traffic accident.
- Assume that once the air pollution exposure is removed (for example, by moving to a cleaner city) their excess risk of dying returns to normal.

Summary

- Each year of living in highly polluted city (e.g. Delhi) reduces expected average life expectancy by 30 to 120 days compared to living in cleaner city (e.g. Zurich)
 - Comparable to effects of being moderate smoker
- Over a lifetime, this amounts to up about 7 years lost life expectancy
